## Tutorial

Jacinda is well-suited to processing the output of Unix tools: regular expressions scan for relevant output and one can split on separators.

There is additionally support for filters, maps and folds that are familiar to functional programmers.

On Mac, one can use `otool -l` to show load commands and then select lines specifying the `name`, extracting the second field:

```
otool -l $(locate libpng.dylib) | ja '{`1 ~ /^name/}{`2}'
```

Using `-F` to specify a custom separator:

```
printenv | ja -F= '{%/^PATH/}{`2}'
```

This gets the value of `PATH`.

## Language

### Patterns + Implicits, Streams

In Jacinda, one writes a pattern and an expression defined on matching lines, viz.

```
{% <pattern>}{<expr>}
```

This defines a stream of expressions.

One can search a file for all occurrences of a string:

```
ja '{% /Bloom/}{`0}' -i ulysses.txt
```

``0` here functions like `$0` in `awk`: it means the whole line.

Thus, the above functions like `ripgrep`. We could imitate `fd` with, say:

```
ls -l -R | ja '{% /\.hs$/}{`0}'
```

This would print all Haskell source files in the current directory.

There is another form,

```
{<expr>}{<expr>}
```

where the initial expression is of boolean type, possibly involving the line context. An example:

```
{#`0>110}{`0}
```

This defines a stream of lines that are more than 110 bytes (`#` is ‘tally’, it returns the length of a string).

There is also a syntax that defines a stream on all lines,

```
{|<expr>}
```

So `{| ``0}` would define a stream of text corresponding to the lines in the file.

## Fold

To count lines with the word “Bloom”:

```
ja '(+)|0 {% /Bloom/}{1}' -i ulysses.txt
```

Note the *fold*, `|`. It is a ternary operator taking `(+)`, `0`, and `{%/Bloom/}{1}` as arguments. The general syntax is:

```
<expr>|<expr> <expr>
```

It takes a binary operator, a seed, and a stream and returns an expression.

There is also `▷`, which folds without a seed.

## Map

Suppose we wish to count the lines in a file.

```
(+)|0 {1}
```

This uses aforementioned `{|<expr>}` syntax. It this defines a stream of `1`s for each line, and takes its sum.

We could also do the following:

```
(+)|0 [:1"$0
```

`$0` is the stream of all lines. `[:` is the constant operator,  $a \rightarrow b \rightarrow a$ , so `[:1` sends anything to `1`.

`"` maps over a stream. So the above maps `1` over every line and takes the sum.

## Functions

We could abstract away `sum` in the above example like so:

```
let val
  sum := [(+)|0 x]
in sum {% /Bloom/}{1} end
```

In Jacinda, one can define functions with a `dfn` syntax in, like in APL. We do not need to bind `x`; the variables `x` and `y` are implicit. Since `[(+)|0 x]` only mentions `x`, it is treated as a unary function.

Note also that `:=` is used for definition. The general syntax is

```
let (val <name> := <expr>)* in <expr> end
```

**Lambdas** There is syntactical support for lambdas;

```
\x. (+)|0 x
```

would be equivalent to `[(+)|0 x]`.

## Zips

The syntax is:

```
, <expr> <expr> <expr>
```

One could (for instance) calculate population density:

```
, (%) $5: $6:
```

The postfix `:` parses the column based on inferred type; here it parses as a float.

## Scans

The syntax is:

```
<expr> ^ <expr> <expr>
```

Scans are like folds, except that the intermediate value is tracked at each step.

One could define a stream containing line numbers for a file with:

```
(+)^0 [:1"$0
```

(this is the same as `{|ix}`)

## Prior

Jacinda has a binary operator, `\.`, like `q`'s `each prior` or `J`'s dyadic infix. One could write:

```
succDiff := [(-) \. x]
```

to track successive differences.

**Currying** Jacinda allows partially applied (curried) functions; one could write

```
succDiff := ((-)\.)
```

## Deduplicate

Jacinda has stream deduplication built in with the `~.` operator.

```
~.$0
```

This is far better than `sort | uniq` as it preserves order; it is equivalent to `!a[$0]++` in `awk`.

## Filter

We can filter an extant stream with `#.`, viz.

```
(>110) #. $1:i
```

`#.` takes as its left argument a unary function returning a boolean.

```
[#x>110] #. $0
```

would filter to those lines `>110` bytes wide.

## Formatting Output

One can format output with `sprintf`, which works like `printf` in Awk or C.

As an example,

```
{|sprintf '%i: %s' (ix.`0)}
```

would display a file annotated with line numbers. Note the atypical syntax for tuples, we use `.` as a separator rather than `,`.

## Libraries

There is a syntax for functions:

```
fn sum(x) :=  
  (+)|0 x;
```

```
fn drop(n, str) :=  
  let val l := #str  
  in substr str n l end;
```

Note the `:=` and also the semicolon at the end of the expression that is the function body.

Since Jacinda has support for higher-order functions, one could write:

```
fn any(p, xs) :=  
  (||)|#f p"xs;
```

```
fn all(p, xs) :=  
  (&)|#t p"xs;
```

**File Includes** One can `@include` files.

As an example, one could write:

```
@include'lib/string.jac'
```

```
fn path(x) :=  
  intercalate '\n' (splitc x ':');
```

```
path"$0
```

intercalate is defined in `lib/string.jac`.

**In-Place File Modification** We could trim whitespace from lines with:

```
(sub1 /\s+$/ 0)"$0
```

`sub1` is like AWK's `sub` and only substitutes the first occurrence. `0` is zilde, and can be used to represent an empty string or vector.

Jacinda does not modify files in-place so one would need to use sponge, viz.

```
ja '(sub1 /\s+$/ 0)'"$0' -i FILE | sponge FILE
```

### Prelude

```
or := [(||)|#f x]
```

```
and := [(&)|#t x]
```

```
count := [(+)|0 [:1"x]
```

`#t` and `#f` are boolean literals.

### System Interaction

Jacinda ignores any line beginning with `#!`, thus one could write a script like so:

```
#!/usr/bin/env -S ja run
```

```
fn path(x) :=  
  ([x+'\n'+y])|> (splitc x ':');
```

```
path"$0
```

## Examples

### Vim Tags

Suppose we wish to generate vim tag files for our Jacinda programs. According to `:help tags-file-format` the desired format is

```
{tagname}      {TAB} {tagfile} {TAB} {tagaddress}
```

where `{tagaddress}` is an ex command. In fact, addresses defined by regular expressions are preferable as they become outdated less quickly.

As an example, suppose we have the function declaration

Our program uses | as a field separator, thus '2 will present us with:

which is exactly the relevant bit.

```
printSpan: ?{% /\|/}{`2}
```

# Unix Command-Line Tools

To get a flavor of Jacinda, see how it can be used in place of familiar tools:

To count lines:

or

To count bytes in a file:

or

head

To emulate `head -n60`, for instance:

**basename**

8

will remove the directory part of a filename.

### **uniq**

```
fn step(acc, this) :=
  if this = acc->1
    then (this . None)
    else (this . Some this);
```

```
(->2):?step^(''.None) $0
```

This tracks the previous line in a state and only adds the current line to the stream if it is different.

### **nl**

We can emulate `nl -b a` with:

```
{|sprintf '    %i %s' (ix.`0)}
```

To count only non-blank lines:

```
fn empty(str) :=
  #str = 0;

fn step(acc, line) :=
  if empty line
    then (acc->1 . '')
    else (acc->1 + 1 . line);

fn process(x) :=
  if !empty (x->2)
    then sprintf '    %i\t%s' x
    else '';
```

```
process"step^(0 . '') $0
```

## **Data Processing**

### **CSV Processing**

We can convert `.csv` data to use ASCII separators with the aid of `xsv`, viz.

```
xsv fmt file.csv --ascii | ja --asv '$1'
```

For “well-behaved” `csv` data, we can simply split on `,`:

```
ja -F, '$1'
```

**Vaccine Effectiveness** As an example, NYC publishes weighted data on vaccine breakthroughs.

We can download it:

```
curl -L https://raw.githubusercontent.com/nychealth/coronavirus-data/master/latest/now-weekly-breakthrough.csv -o /tmp/now-weekly-breakthrough.csv
```

And then process its columns with `ja`

```
ja '[1.0-x%y] {ix>1}{`5:} {ix>1}{`11:}' -F, -i /tmp/now-weekly-breakthrough.csv
```

As of writing:

```
0.8793436293436293
0.8524501884760366
0.8784741144414169
0.8638045891931903
0.8644207066557108
0.8572567783094098
0.8475274725274725
0.879263670817542
0.8816131830008673
0.8846732911773563
0.8974564390146205
0.9692181407757029
```

This extracts the 5th and 11th columns (discarding headers), and then computes effectiveness.

**Inflation** We start with New Zealand’s food price index:

```
curl -O https://www.stats.govt.nz/assets/Uploads/Food-price-index/Food-price-index-September-2023/Download-data/food-price-index-september-2023-weighted-average-prices.csv
```

This data is not “well-behaved” so we convert to ASV:

```
xsv fmt --ascii food-price-index-september-2023-weighted-average-prices.csv | ja --
asv '(%)\. {%/Apple/}{`3:}'
```

This uses `(\.)` (prior) to do something `xsv` cannot.

## Machinery

### Typeclasses

Under the hood, Jacinda has typeclasses, inspired by Haskell. These are used to disambiguate operators and witness with an implementation.

The language does not allow custom typeclasses.

## Functor

The map operator " works on all functors, not just streams. `Stream`, `List`, and `Option` are instances.

## IsPrintf

The `IsPrintf` typeclass is used to type `sprintf`; strings, integers, floats, booleans, and tuples of such are members.

```
sprintf '%i' 3
```

and

```
sprintf '%s-%i' ('str' . 2)
```

are both valid.

## Row Types

The  $\rightarrow n$  accessors work on all applicable tuples, so

```
(a.b.c)->2
```

and

```
(a.b)->2
```

are both valid.

Moreover,

```
(a.b)->3
```

will be caught during typechecking.
