#### **Tutorial**

Jacinda has fluent support for filters, maps and folds that are familiar to functional programmers; the syntax in particular is derivative of J or APL.

Jacinda is at its best when piped through other command-line tools (including awk).

#### Language

#### Patterns + Implicits, Streams

Awk is oriented around patterns and actions. Jacinda has support for a similar style: one defines a pattern and an expression defined by the lines that this matches, viz.

```
{% <pattern>}{<expr>}
```

This defines a stream of expressions.

One can search a file for all occurrences of a string:

```
ja '{% /Bloom/}{`0}' -i ulysses.txt
```

'0 here functions like \$0 in awk: it means the whole line.

Thus, the above functions like ripgrep. We could imitate fd with, say:

```
ls -1 -R | ja '\{\% /\.hs\/\}\{\0\}'
```

This would print all Haskell source files in the current directory.

There is another form,

```
{<expr>}{<expr>}
```

where the initial expression is of boolean type, possibly involving the line context. An example:

```
{#`0>110}{`0}
```

This defines a stream of lines that are more than 110 bytes (# is 'tally', it returns the length of a string).

There is also a syntax that defines a stream on all lines,

```
{|<expr>}
```

So {|``0} would define a stream of text corresponding to the lines in the file.

#### Fold

Then, count lines with the word "Bloom":

```
ja '(+)|0 {% /Bloom/}{1}' -i ulysses.txt
```

Note the fold, |. It is a ternary operator taking (+), 0, and {% /Bloom/}{1} as arguments. The general syntax is:

```
<expr>|<expr> <expr>
```

It takes a binary operator, a seed, and a stream and returns an expression.

There is also |>, which folds without a seed.

#### Map

Suppose we wish to count the lines in a file. We have nearly all the tools to do so:

```
(+) | 0 { | 1}
```

This uses aforementioned {|<expr>} syntax. It this defines a stream of 1s for each line, and takes its sum.

We could also do the following:

```
(+) | 0 [:1"$0
```

0 is the stream of all lines. [: is the constant operator,  $a \rightarrow b \rightarrow a$ , so [:1 sends anything to 1.

#### **Functions**

We could abstract away sum in the above example like so:

```
let val
  sum := [(+)|0 x]
in sum {% /Bloom/}{1} end
```

In Jacinda, one can define functions with a dfn syntax in, like in APL. We do not need to bind x; the variables x and y are implicit. Since <code>[(+)|0 x]</code> only mentions x, it is treated as a unary function.

Note also that := is used for definition. The general syntax is

```
let (val <name> := <expr>)* in <expr> end
```

**Lambdas** There is syntactical support for lambdas;

```
\xumber{x} (+) | 0 x
```

would be equivalent to the above example.

<sup>&</sup>quot; maps over a stream. So the above maps 1 over every line and takes the sum.

#### Zips

The syntax is:

, <expr> <expr> <expr>

One could (for instance) calculate population density:

, (%) \$5:f \$6:f

The postfix: parses the column based on inferred type; here it parses as a float.

#### Scans

The syntax is:

Scans are like folds, except that the intermediate value is tracked at each step. One could define a stream containing line numbers for a file with:

(this is the same as {|ix})

#### Prior

Jacinda has a binary operator,  $\backslash$ ., like q's each prior or J's dyadic infix. One could write:

```
succDiff := [(-) \setminus x]
```

to track successive differences.

Currying Jacinda allows partially applied (curried) functions; one could write succDiff := ((-)\.)

#### Deduplicate

Jacinda has stream deduplication built in with the ~. operator.

~.\$0

This is far better than sort | uniq as it preserves order; it is equivalent to !a[\$0]++ in awk.

#### Filter

We can filter an extant stream with #., viz.

(>110) #. \$1:i

#. takes as its left argument a unary function returning a boolean.

```
[#x>110] #. $0
```

would filter to those lines >110 bytes wide.

#### Formatting Output

One can format output with sprintf, which works like printf in Awk or C.

As an example,

```
{|sprintf '%i: %s' (ix.`0)}
```

would display a file annotated with line numbers. Note the atypical syntax for tuples, we use . as a separator rather than ,.

#### Libraries

There is a syntax for functions:

```
fn sum(x) :=
   (+) |0 x;

fn drop(n, str) :=
  let val l := #str
   in substr str n l end;
```

Note the := and also the semicolon at the end of the expression that is the function body.

Since Jacinda has support for higher-order functions, one could write:

```
fn any(p, xs) :=
  (||)|#f p"xs;
fn all(p, xs) :=
  (&)|#t p"xs;
```

File Includes One can @include files.

As an example, one could write:

```
@include'lib/string.jac'
fn path(x) :=
  intercalate '\n' (splitc x ':');
path"$0
```

intercalate is defined in lib/string.jac.

**Example** Suppose we want to mimic some functionality of sed - we'd like to replace some regular expression with a string (no capture groups, only first replacement per line)

```
@include'prelude/fn.jac'
fn replace1(re, str, line) :=
  let
    val insert := \line. \str. \ixes.
        take (ixes->1) line + str + drop (ixes->2) line
    in option line (insert line str) (match line re) end;
Then we could trim whitespace from a file with
@include'lib/sed.jac'
(replace1 /\s+$/ '')"$0
Jacinda does not modify files in-place so one would need to use sponge perhaps:
ja run trimwhitespace.jac -i FILE | sponge FILE

Parting Shots
or := [(||)|#f x]
and := [(&)|#t x]
count := [(+)|0 [:1"x]
```

#### System Interaction

#t and #f are boolean literals.

Jacinda ignores any line beginning with #!, thus one could write a script like so:

```
#!/usr/bin/env -S ja run
fn path(x) :=
   ([x+'\n'+y])|'' (splitc x ':');
path"$0
```

### Examples

#### Error Span

Suppose we wish to extract span information from compiler output for editor integration. Vim ships with a similar script, mve.awk, to present column

information in a suitable format.

```
src/Jacinda/Backend/TreeWalk.hs:319:58: error:
    • The constructor 'TyArr' should have 3 arguments, but has been given 4
    • In the pattern:
        TyArr _ _ (TyArr _ (TyApp _ (TyB _ TyStream) _)) _
      In the pattern:
        TyArr _ _ (TyArr _ _ (TyArr _ (TyApp _ (TyB _ TyStream) _)) _)
      In the pattern:
        TBuiltin (TyArr _
                          (TyArr _ _ (TyArr _ (TyApp _ (TyB _ TyStream) _)) _))
                  Fold
^{.} 319 \mid eWith re i (EApp \_ (EApp \_ (EApp \_ (TBuiltin (TyArr \_ _ (TyArr \_ _ (TyArr \_ _ (TyApp \_
To get what we want, we use match, which returns indices that match a regex -
in our case, /\^+/, which spans the error location.
From the manpages, we see it has type
match : Str -> Regex -> Option (Int . Int)
:set fs:=///;
fn printSpan(str) :=
  (sprintf '%i-%i')"(match str /\^+/);
printSpan:?{% /\|/}{`2}
Our program uses | as a file separator, thus '2 will present us with:
which is exactly the relevant bit.
First, note that " is used to map (sprintf '%i-%i') over (match ...). This
works because match returns an Option, which is a functor. The builtin: ? is
mapMaybe. Thus, we define a stream
printSpan:?{% /\|/}{`2}
which only collects when printSpan returns a Some.
Vim Tags
```

Suppose we wish to generate vim tag files for our Jacinda programs. According to :help tags-file-format the desired format is

```
{tagname}
                {TAB} {tagfile} {TAB} {tagaddress}
```

where {tagaddress} is an ex command. In fact, addresses defined by regular expressions are preferable as they become outdated less quickly.

As an example, suppose we have the function declaration

```
fn sum(x) :=
  (+)|0 x;
```

Then we need to extract sum and give a regex that points to where it is defined.

To do so:

```
fn mkEx(s) :=
   '/^' + s + '$/;';

fn processStr(s) :=
   let
    val line := split s /[ \( \) \( \) \( \) \( \) val outLine := sprintf '%s\t%s\t%s' (line.2 . fp . mkEx s) in outLine end;

processStr"{%/fn +[[:lower:]][[:latin:]]*.*:=/}{^0}

Note the builtin split; according to the manpages it has type split : Str -> Regex -> List Str
   .2 is the syntax for accessing a list - line.2 extracts the second element.
```

#### **Unix Command-Line Tools**

To get a flavor of Jacinda, see how it can be used in place of familiar tools:

```
grep
ja '{%/the/}{`0}' -i FILE
wc
To count lines:
(+)|0 [:1"$0
or
[y]|0 {|ix}
To count bytes in a file:
(+)|0 [#x+1]"$0
or
(+)|0 {|#`0+1}
```

#### head

```
To emulate head -n60, for instance:
{ix<=60}{^0}
uniq
fn step(acc, this) :=
  if this = acc->1
    then (this . None)
    else (this . Some this);
(->2):?step^(''.None) $0
```

This tracks the previous line in a state and only adds the current line to the stream if it is different.

#### nl

```
We can emulate nl -b a with:
               %i %s' (ix.`0)}
{|sprintf '
To count only non-blank lines:
fn empty(str) :=
  #str = 0;
fn step(acc, line) :=
  if empty line
    then (acc->1 . '')
    else (acc\rightarrow1 + 1 . line);
fn process(x) :=
  if !empty (x->2)
    then sprintf '
                       %i\t%s' x
    else '';
process"step^(0 . '') $0
```

#### **Data Processing**

### **CSV Processing**

```
We can process .csv data with the aid of csvformat, viz. csvformat file.csv -D'|' | ja -F'\|' '$1'
For "well-behaved" csv data, we can simply split on ,:
```

```
ja -F, '$1'
```

**Vaccine Effectiveness** As an example, NYC publishes weighted data on vaccine breakthroughs.

We can download it:

curl -L https://raw.githubusercontent.com/nychealth/coronavirus-data/master/latest/now-week

And then process its columns with ja

ja ',[1.0-xy] {ix>1}{`5:} {ix>1}{`11:}' -F, -i /tmp/now-weekly-breakthrough.csv As of writing:

- 0.8793436293436293
- 0.8524501884760366
- 0.8784741144414169
- 0.8638045891931903
- 0.8644207066557108
- 0.8572567783094098
- 0.8475274725274725
- 0.879263670817542
- 0.8816131830008673
- 0.8846732911773563
- 0.8974564390146205
- 0.9692181407757029

This extracts the 5th and 11th columns (discarding headers), and then computes effectiveness.

### Machinery

Under the hood, Jacinda has typeclasses, inspired by Haskell. These are used to disambiguate operators and witness with an implementation.

The language does not allow custom typeclasses.

#### **Functor**

The map operator " is works on all functors, not just streams. Stream, List, and Option are instances.

#### **IsPrintf**

The IsPrintf typeclass is used to type sprintf; strings, integers, floats, booleans, and tuples of such are members.

sprintf '%i' 3

```
and sprintf '%s-%i' ('str' . 2) are both valid.
```
